

# Mitochondria and the production of ATP

Alexandra Harci

# **THE STRUCTURE OF MITOCHONDRIA**

# The mitochondrion

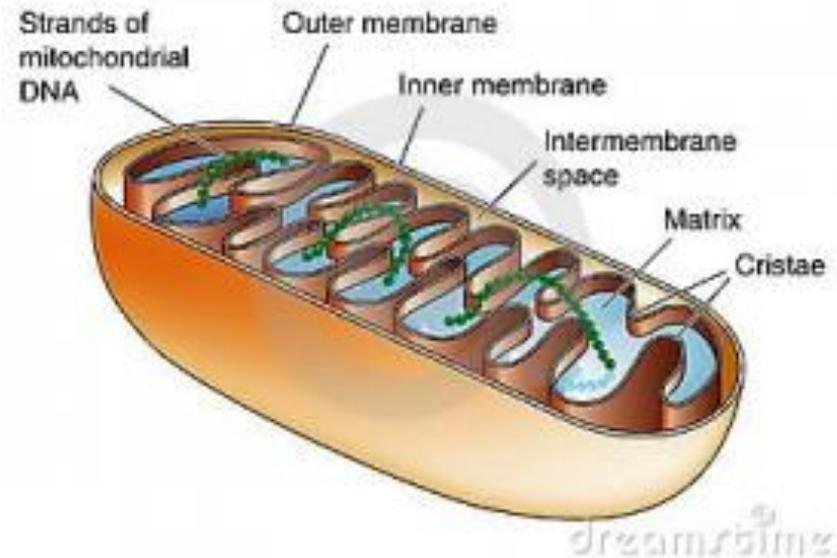

- Greek Mito = „thread“, and chondrion = „granule“
- found in most eukaryotic cells
- „energy factory of the cell“
- 0.5 to 1.0 micrometer ( $\mu\text{m}$ )
- Number: 1- several thousand /cell

BA3200 [RM] © www.visualphotos.com

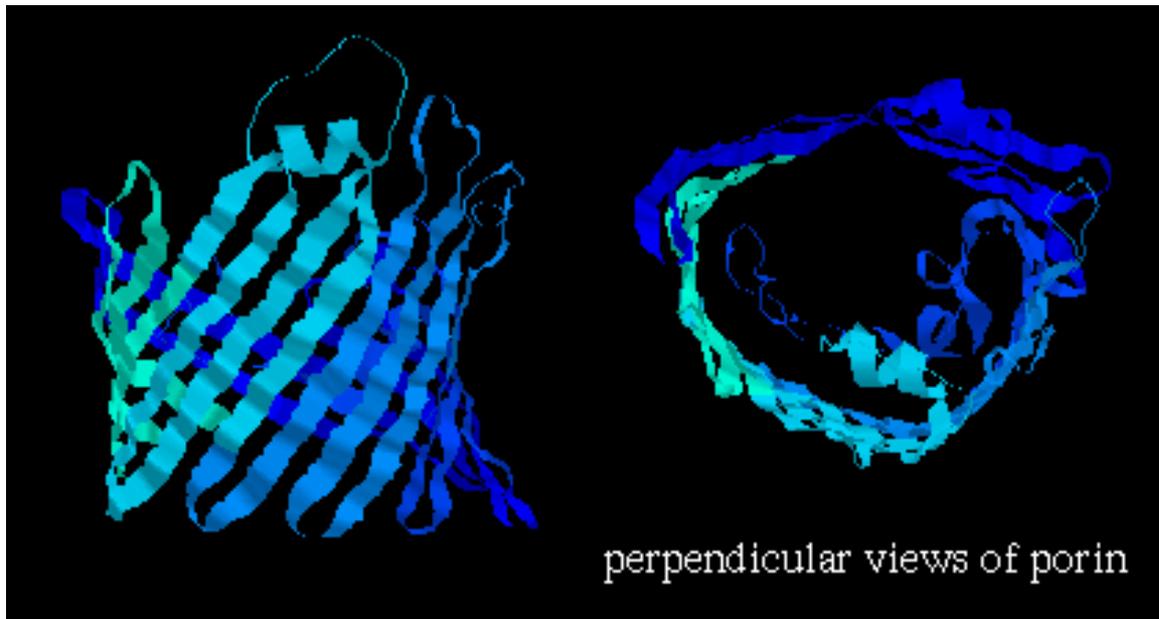

# The mitochondrion

- Surrounded by a double membrane:
  1. Outer membrane
  2. Intermembrane space
  3. Inner membrane (cristae)
  4. Mitochondrial matrix

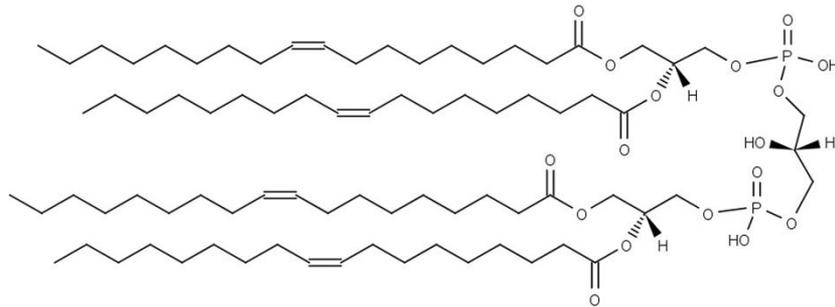

# 1. Outer membrane

- similar to the eukaryotic plasma membrane (protein:phospholipid = 1:1)
- Contain porin proteins → make the membrane permeable to 10.000 Dalton

## 2. Inner membrane

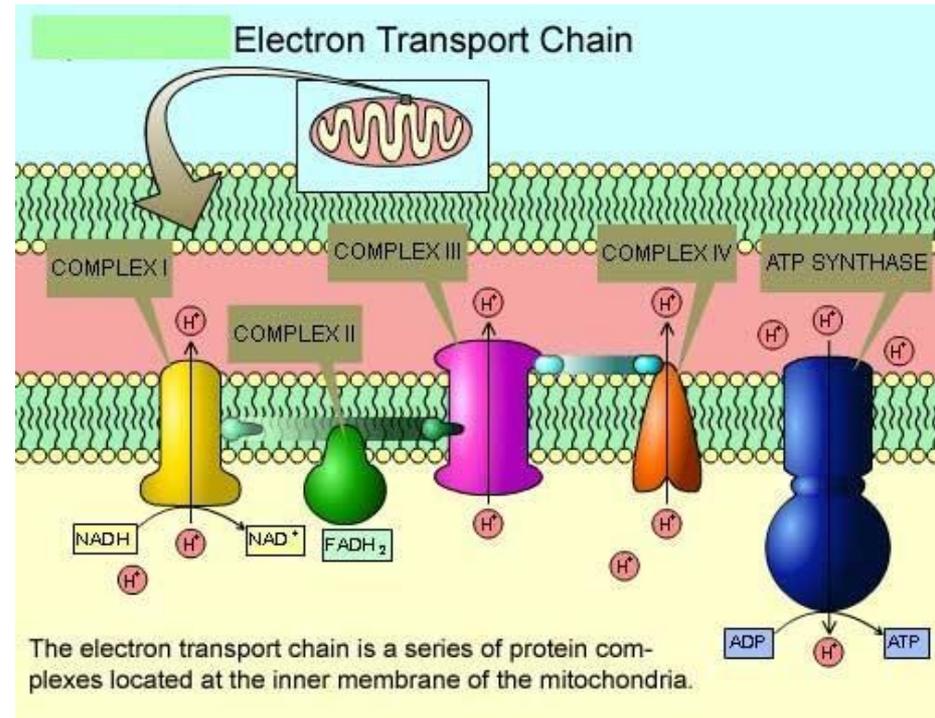

Cardiolipin  
1',3'-Bis-[1,2-di-(9Z-octadecenoyl)-sn-glycero-3-phospho]-sn-glycerol

- protein:phospholipid = 80:20
- rich in cardiolipin (phospholipid) → makes the inner membrane impermeable
- molecules require special transport proteins to enter or exit the matrix
- forms cristae

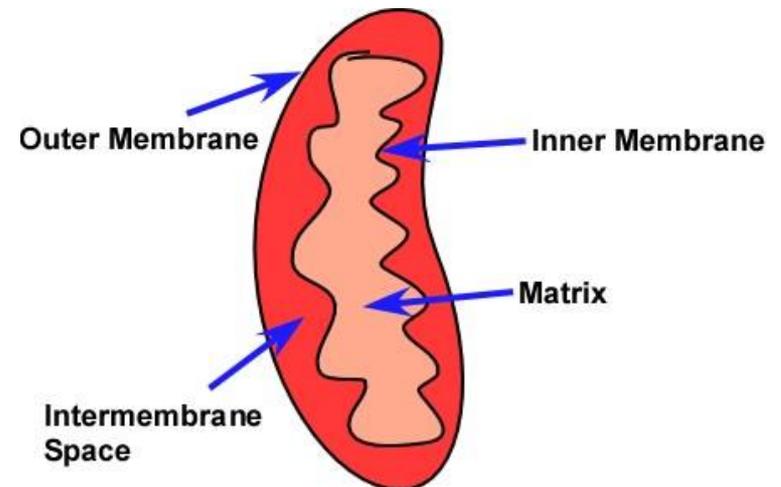

# 2. Inner membrane

- Cristae
  - expand the surface area of the inner mitochondrial membrane
  - Contain proteins:
    - Specific transport proteins
    - Proteins of the electron transport chain
    - ATP-synthase

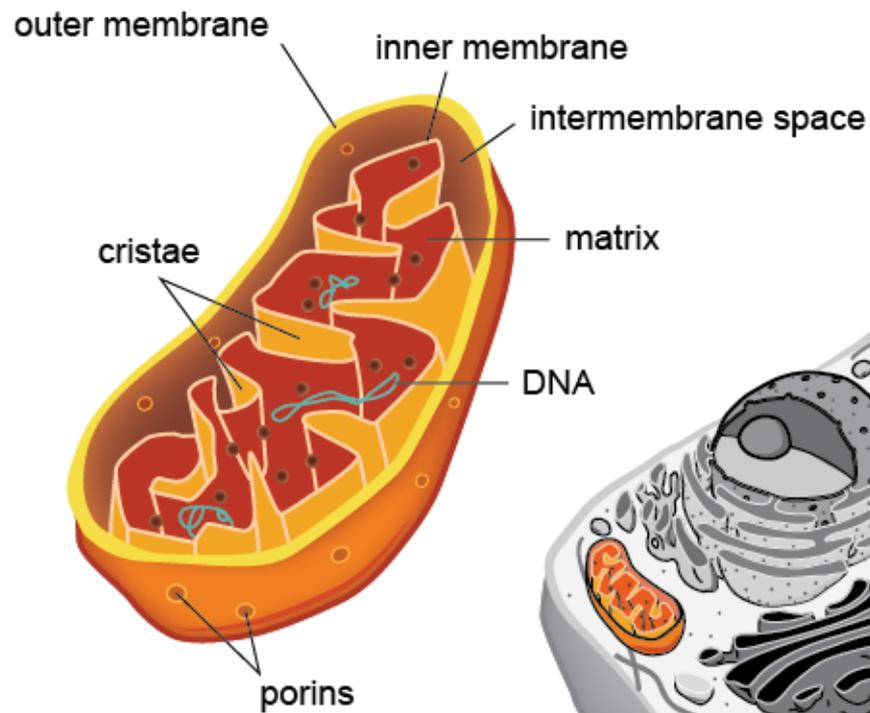

# 3. Intermembrane space

- Between the outer membrane and the inner membrane
- the concentrations of molecules in the intermembrane space is the same as in the cytosol

# 4. Matrix

- Gel-like
- Contains:
  - hundreds of enzymes
  - special mitochondrial ribosomes, tRNAs and mRNAs
  - several copies of the mitochondrial DNA genome

# **THE SYNTHESIS OF ATP**

# The synthesis of ATP

- From glucose and fatty acids

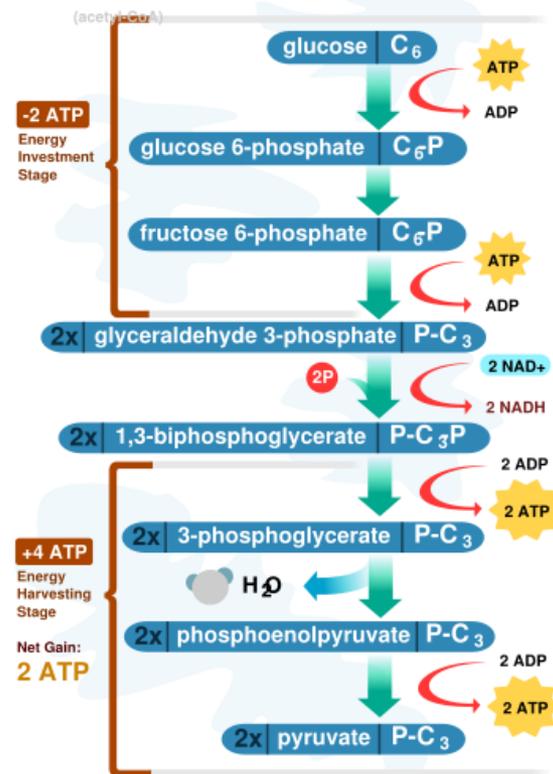

- 3 main processes:

1. Glycolysis

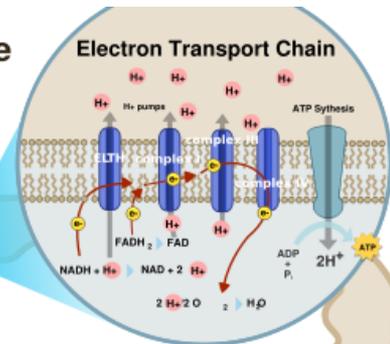

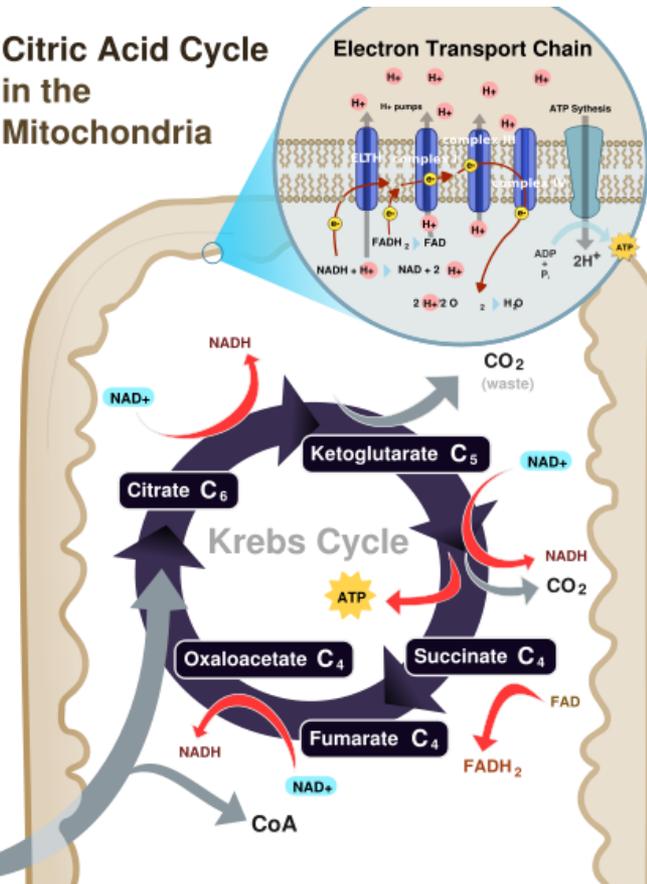

2. Citric acid cycle

3. Terminal oxidation

## Glycolysis in the Cytoplasm

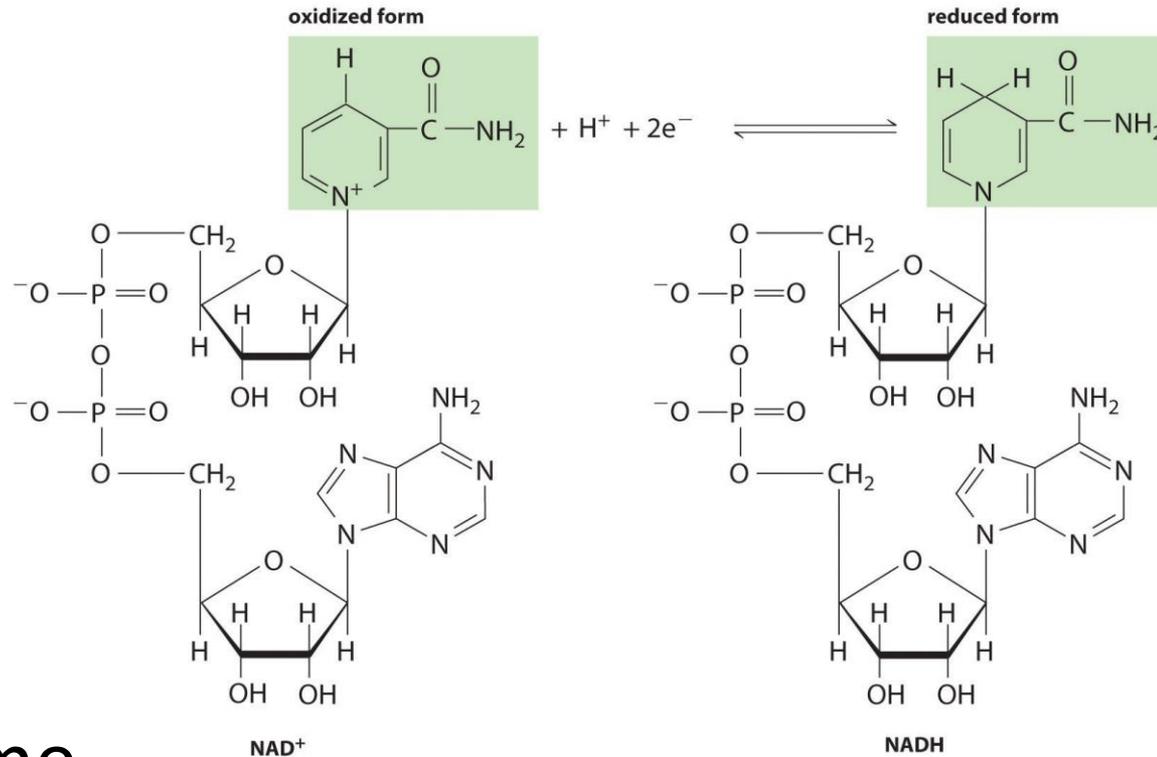

## Citric Acid Cycle in the Mitochondria

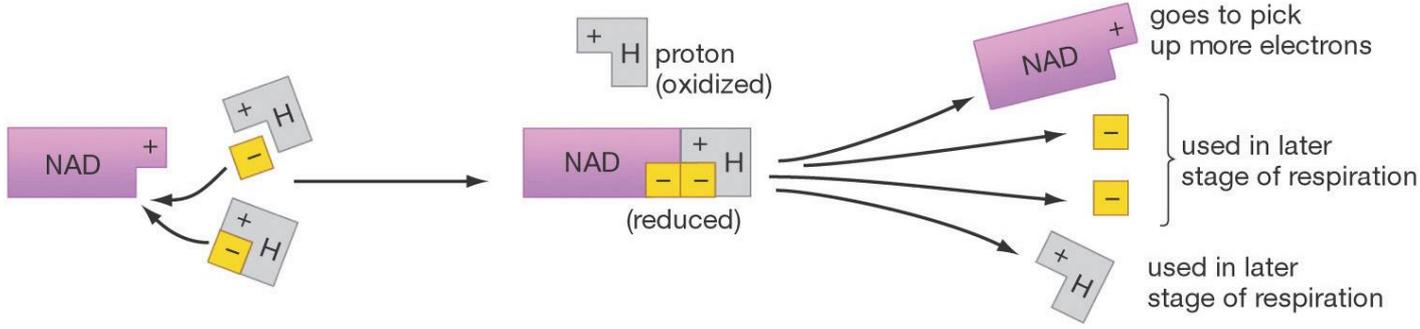

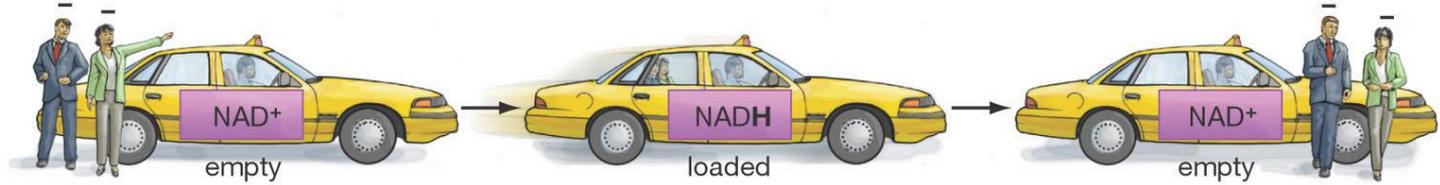

# NAD<sup>+</sup>

(Nicotinamide adenine dinucleotide)

- Coenzyme
- transports electrons from one reaction to another

# NADH (Nicotinamide adenine dinucleotide)

1.  $NAD^+$  within a cell, along with two hydrogen atoms that are part of the food that is supplying energy for the body.

2.  $NAD^+$  is reduced to NAD by accepting an electron from a hydrogen atom. It also picks up another hydrogen atom to become NADH.

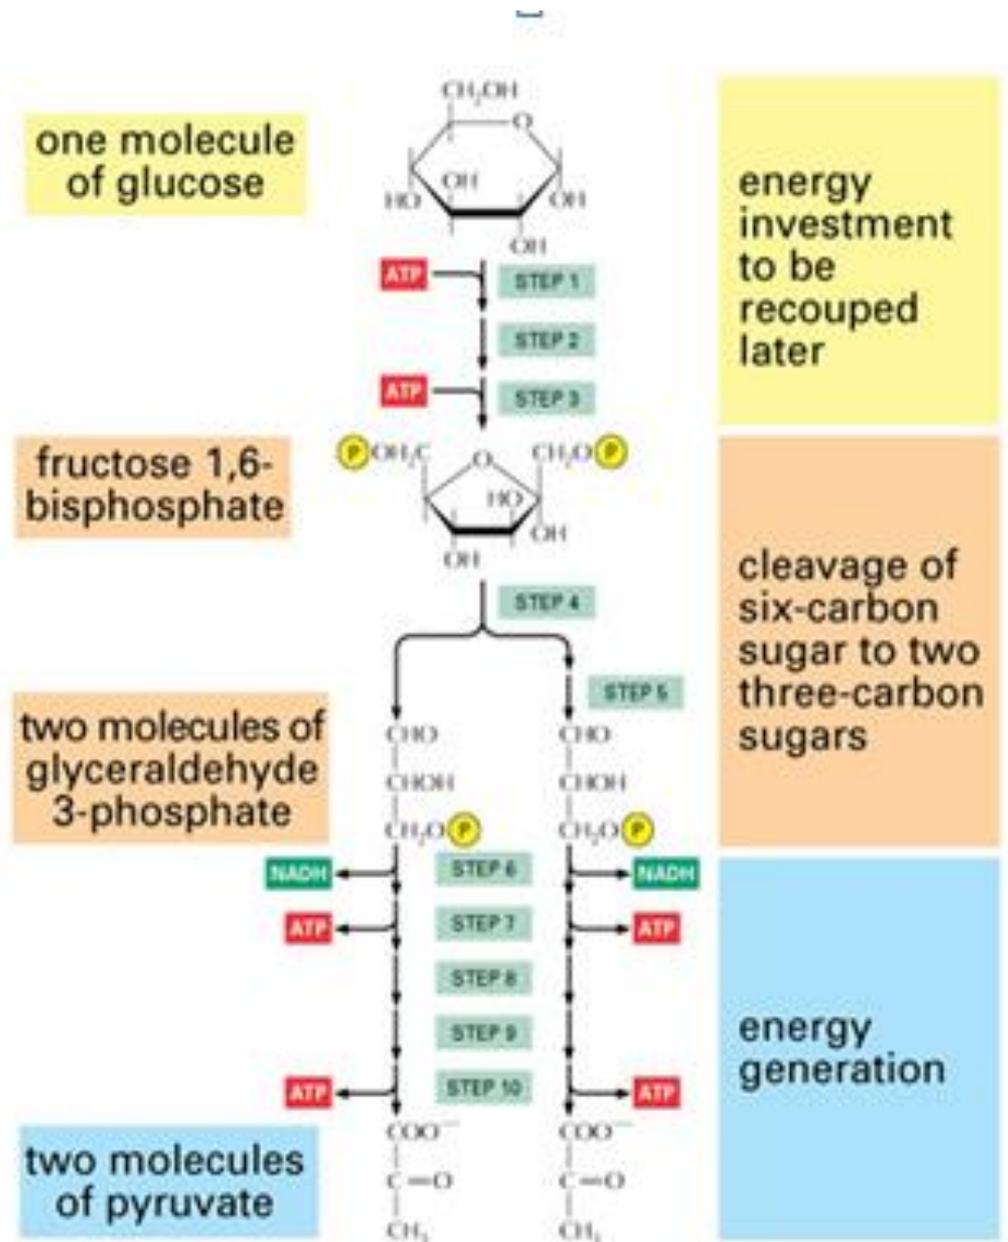

3. NADH carries the electrons to a later stage of respiration then drops them off, becoming oxidized to its original form,  $NAD^+$ .

Copyright © 2005 Pearson Prentice Hall, Inc.

- $NAD^+ \rightarrow$  accepts electrons from other molecules and becomes reduced  $\rightarrow$  NADH
- NADH  $\rightarrow$  donate electrons and becomes oxidized to its original form  $\rightarrow$   $NAD^+$

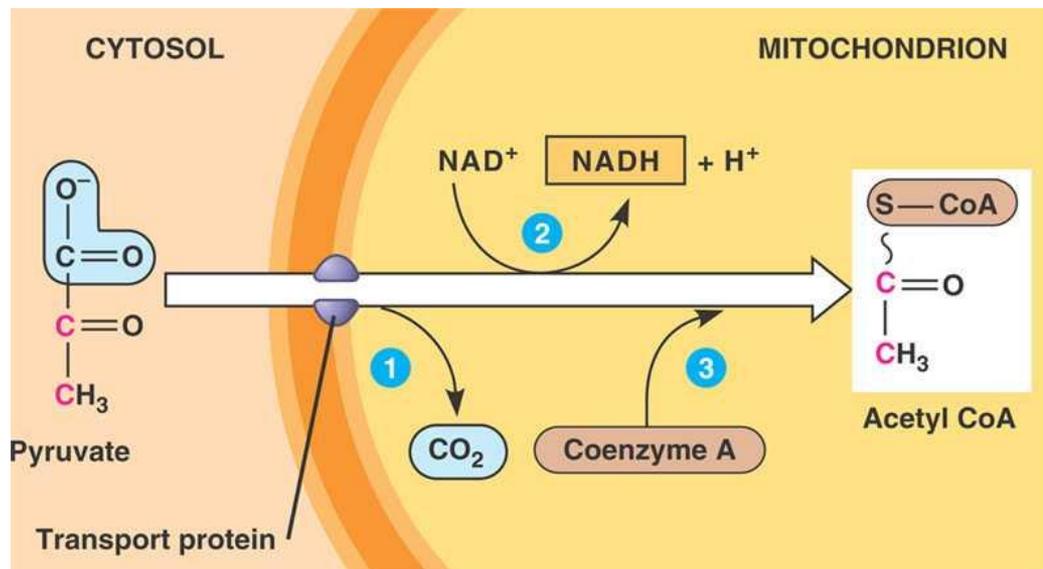

# 1. Glycolysis

- converts glucose ( $C_6$ ) into pyruvate ( $C_3$ )
- in the cytosol
- oxygen is never involved in the reaction
- ten reactions  $\rightarrow$  ten intermediate compounds
- formation of 2 ATPs (4-2) and 2 NADHs, 2 pyruvates

## 2. Citric acid cycle/ Szent-Györgyi and Krebs cycle

- in the matrix of the mitochondrion
- Pyruvate (C<sub>3</sub>) loses 1 carbon atom → acetic acid (C<sub>2</sub>)
- Acetic acid + Coenzyme A (CoA) → Acetyl CoA

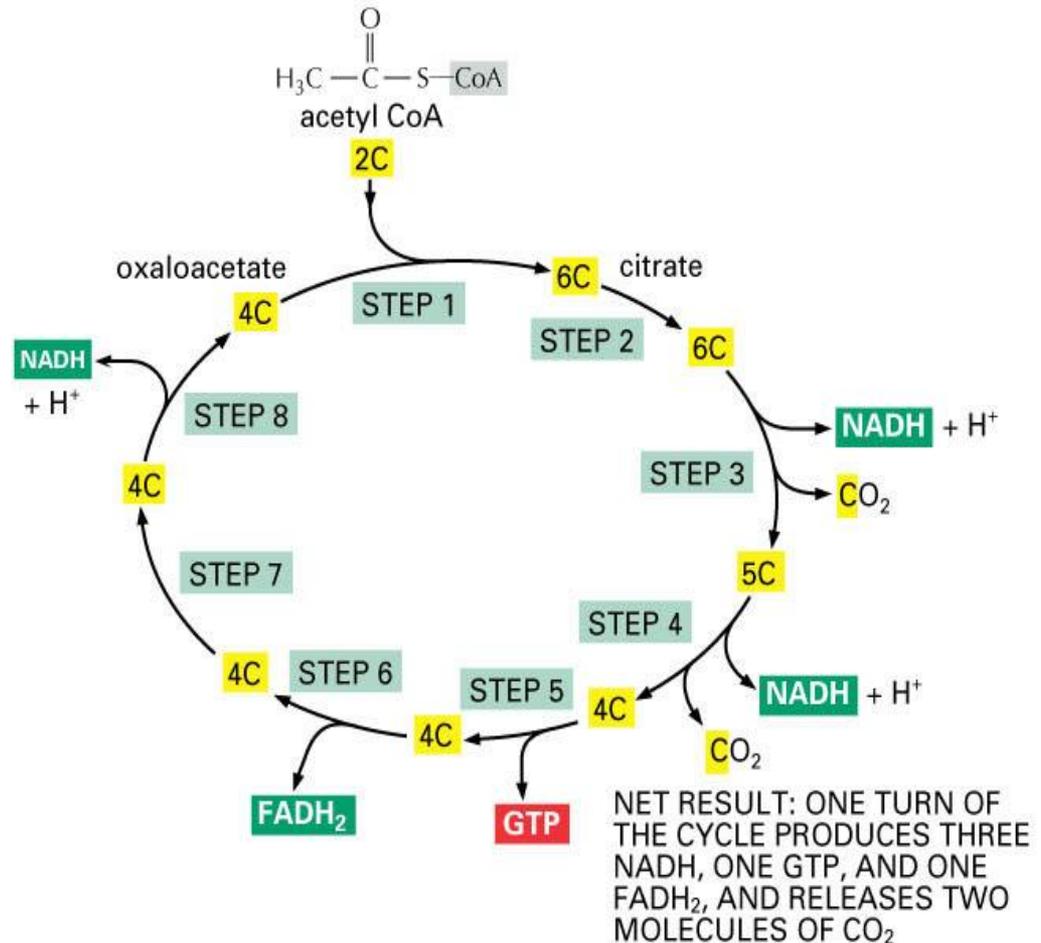

# 2. Citric acid cycle/ Szent-Györgyi and Krebs cycle

- Oxaloacetate (C<sub>4</sub>) + acetyl group (C<sub>2</sub>) = citrate (C<sub>6</sub>)

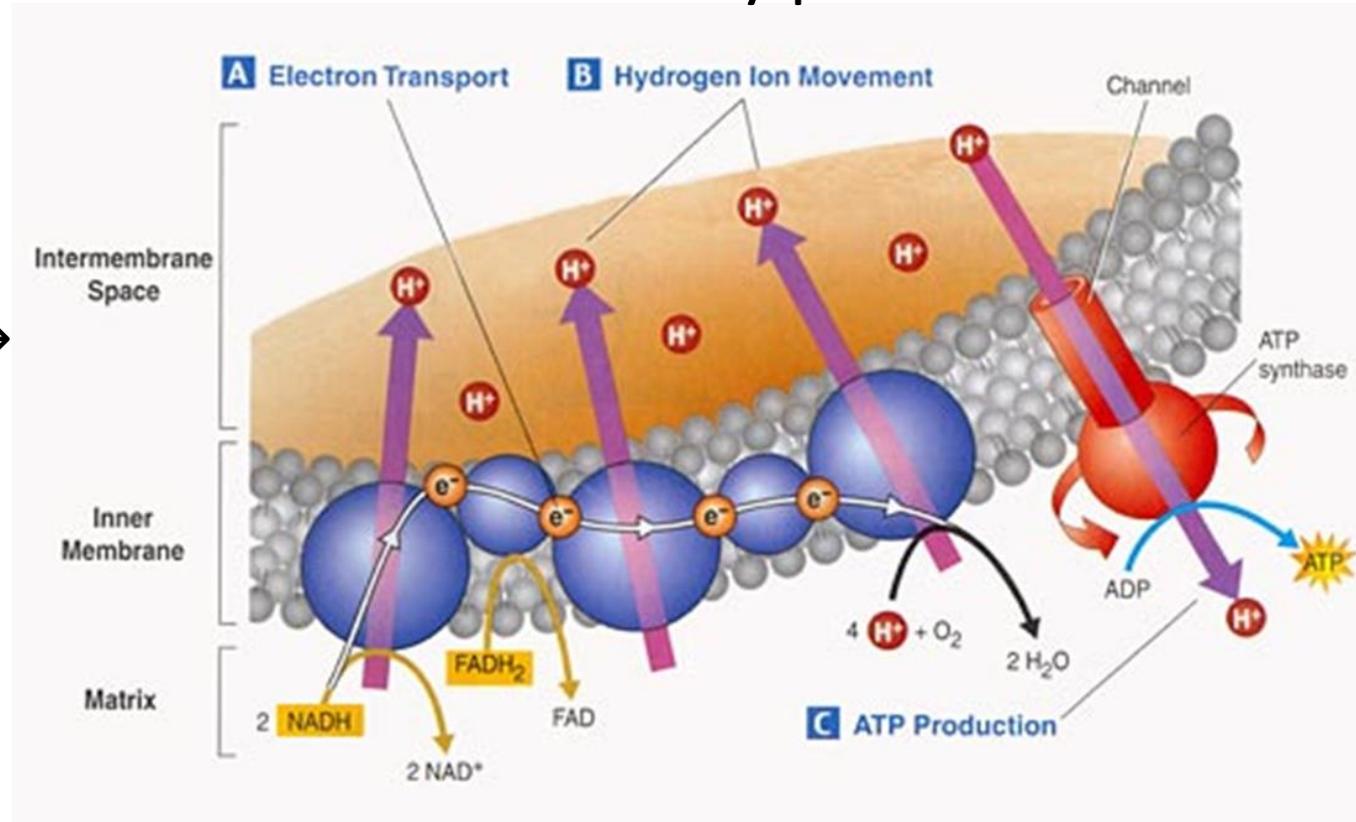

- Formation of:

- 2 CO<sub>2</sub>
- 3 NADH
- 1 FADH<sub>2</sub>
- 1 GTP

# 3. Terminal oxidation / Oxidative phosphorylation

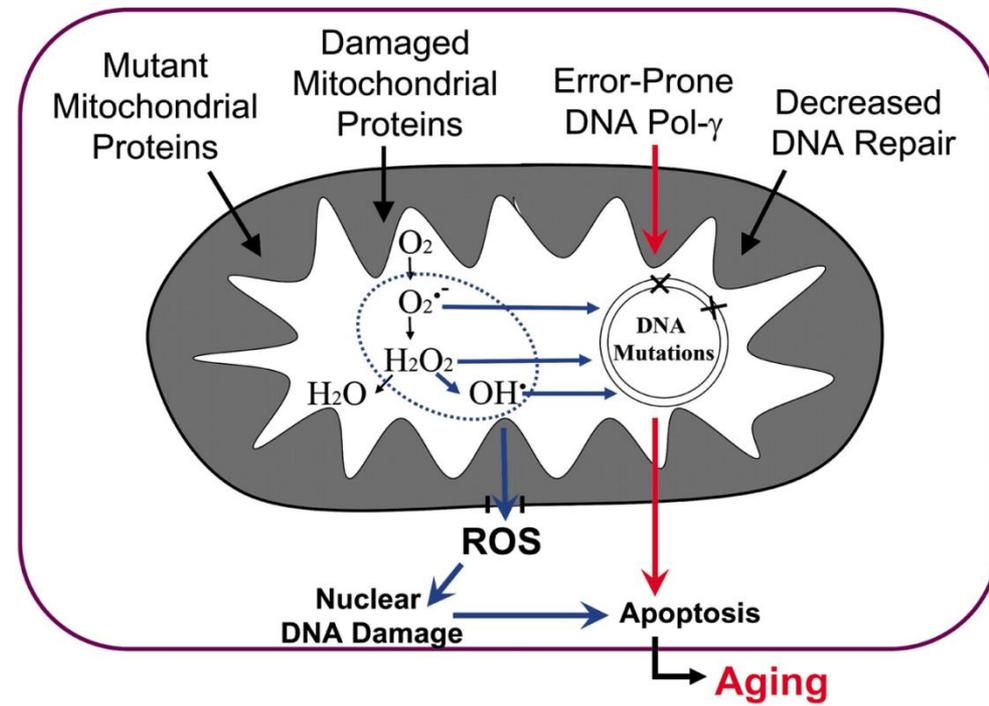

- In the inner mitochondrial membrane by protein complexes
- 3 events:
  - a) Oxidation of coenzymes → transport of the electrons

The final electron acceptor is molecular oxygen → is reduced to water (harmful intermediates are generated =ROS)

# Reactive oxygen species (ROS)

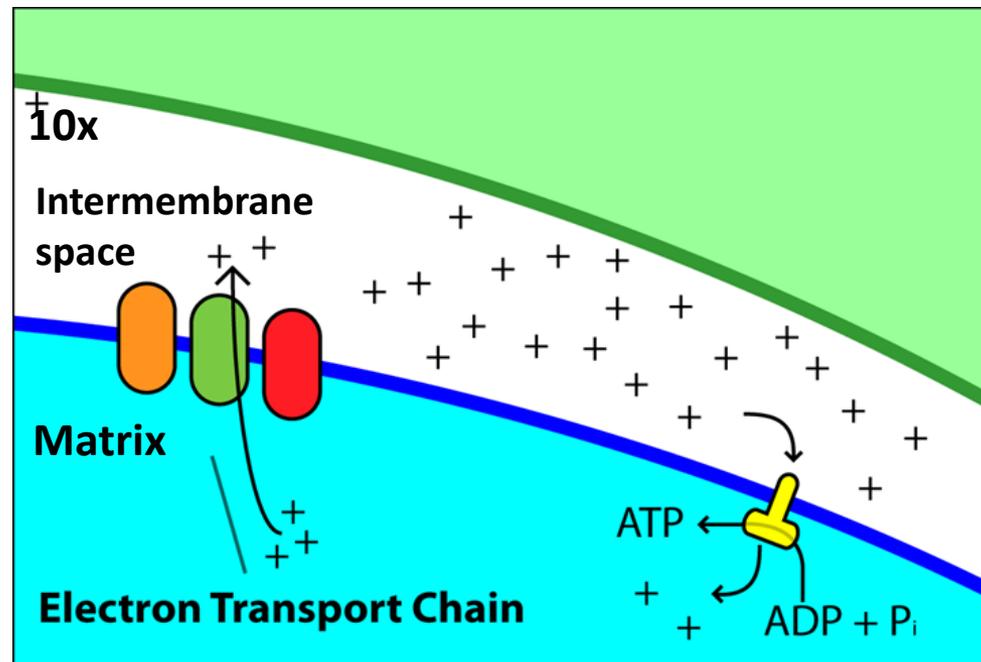

- During reduction of oxygen → harmful, instable intermediates are produced (superoxide or peroxide anions)
- These are called reactive oxygen species (ROS):
  - are very harmful to cells
  - oxidize proteins, destroy the membrane and cause mutations in DNA
  - Cause diseases and is proposed as one cause of aging

# 3. Terminal oxidation / Oxidative phosphorylation

## b) Movement of protons:

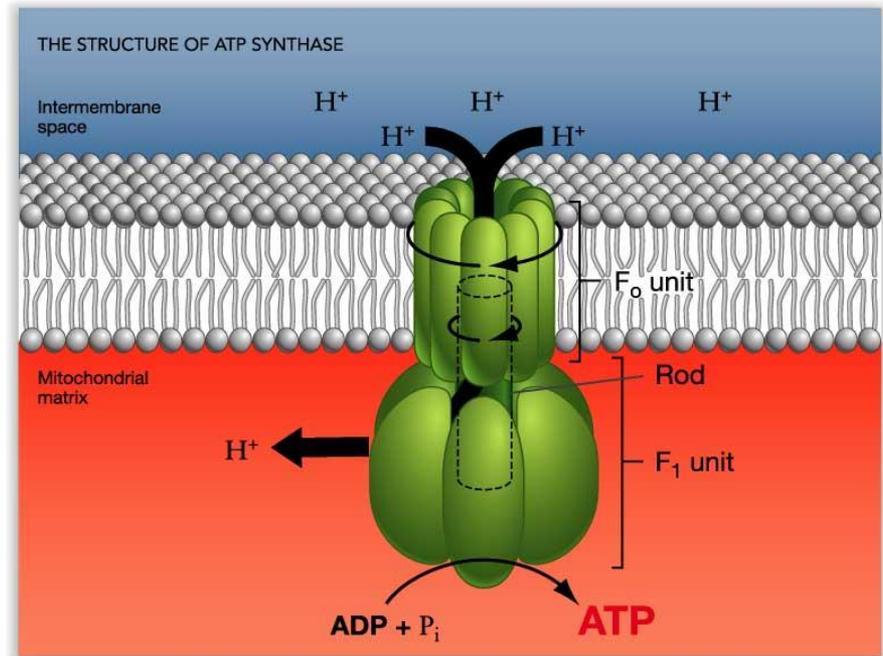

- Are pumped into the intermembrane space → electrochemical proton gradient (proton-motive force)
- Protons have to flow back into the matrix through ATP synthase

# 3. Terminal oxidation / Oxidative phosphorylation

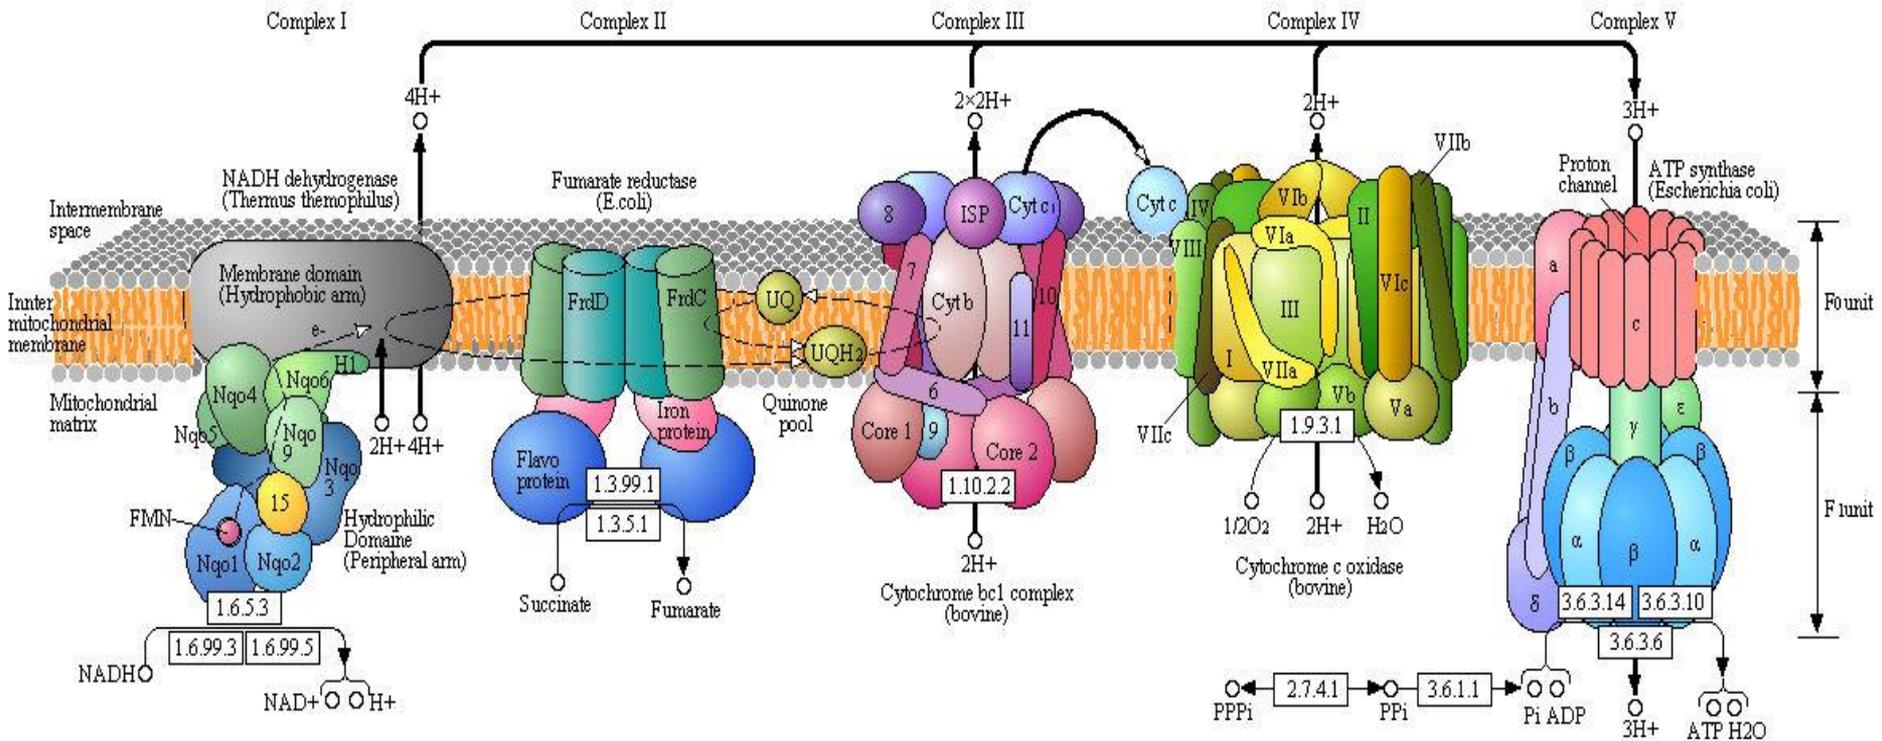

## c) ATP synthesis by ATP synthase:

- Enzyme complex
- $F_0$ : proton channel
- $F_1$ : catalytic activity

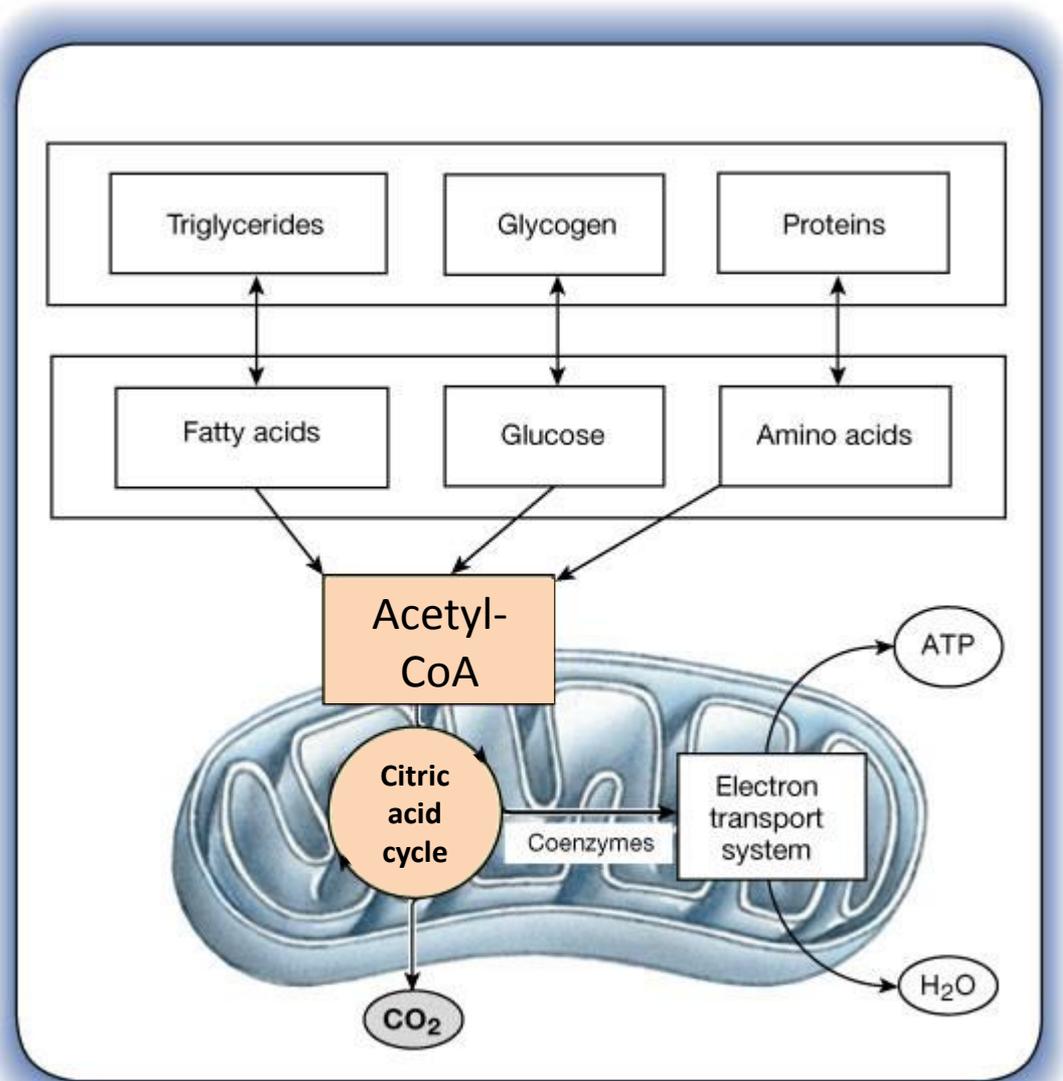

- Protons flow through the complex (chemiosmosis) → this kinetic energy rotates the  $F_1$  subunit → synthesis of ATP from  $ADP + P_i$

# Subunits of the electron transport chain

# ATP production from bioorganic molecules

- 1 g fatty acid:  
9Kcal/37kj
- 1 g carbohydrate:  
4Kcal/17kj
- 1 g protein:  
4Kcal/17kj

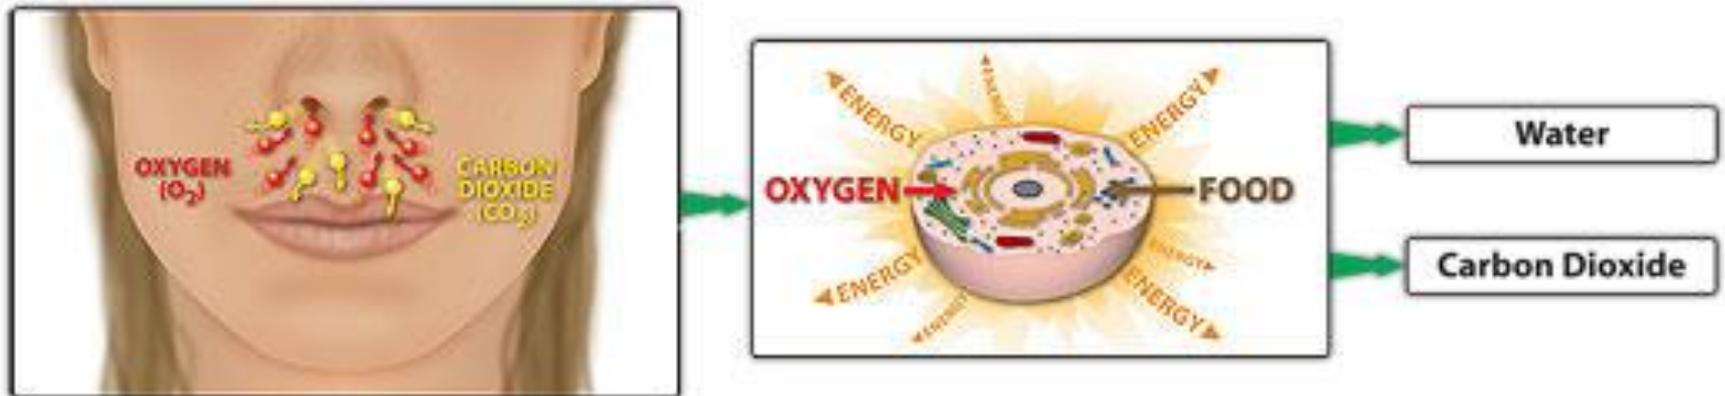

# Fully oxidation of 1 glucose molecule into $\text{CO}_2$

- Glycolysis:
  - Production of 4 ATP but 2 are consumed  $\rightarrow$  2 ATP
- Citric acid cycle:
  - 2 ATP (indirectly)
- Oxidative phosphorylation:
  - 30 or 32 ATP

$\rightarrow$  34 or 36 ATP molecules

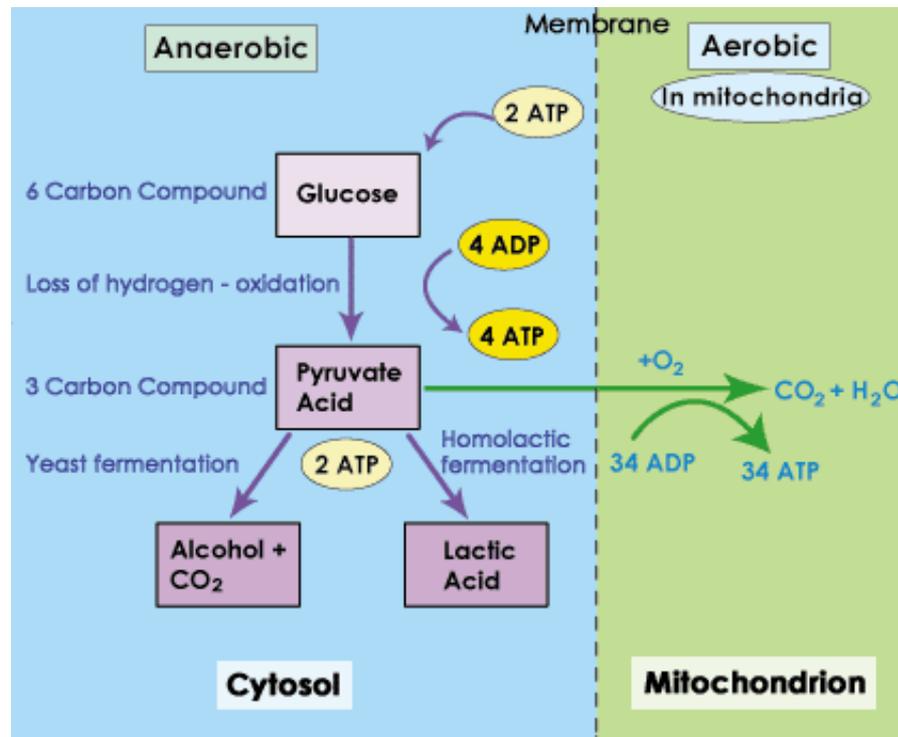

# Aerobic organisms

- requires oxygen to grow
- use oxygen to make energy (cellular respiration)
- Produce more energy than anaerobes  $\leftrightarrow$  high levels of oxidative stress

# Facultative anaerobic organisms

- make ATP by aerobic respiration if oxygen is present
- switch to fermentation if oxygen is not present

# Additional functions

Mitochondria play a central role in many other metabolic tasks:

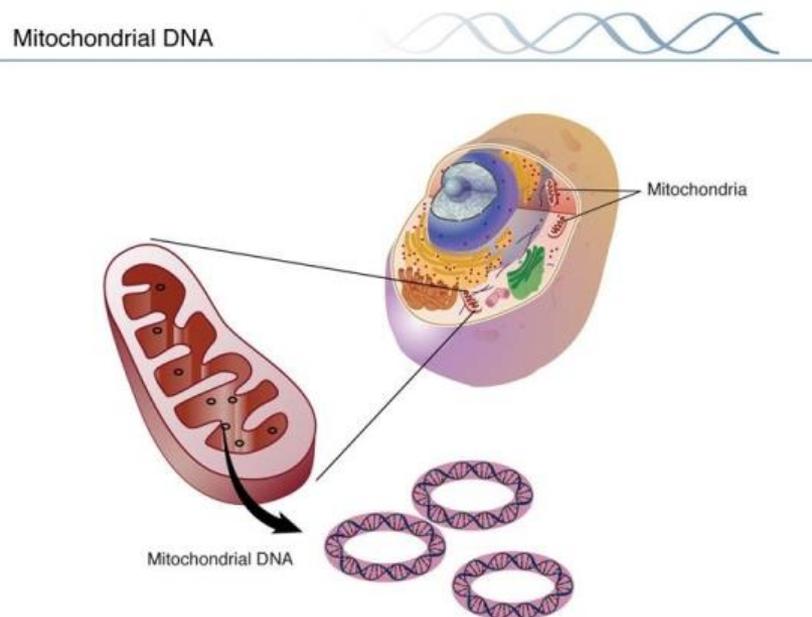

- Regulation of the membrane potential
- Apoptosis (programmed cell death)
- Signaling (regulation of gene expression)
- Regulation of cellular metabolism
- Steroid synthesis
- ...

→ mutation in the genes regulating any of these functions can cause mitochondrial diseases

# **GENETIC APPARATUS OF MITOCHONDRIA**

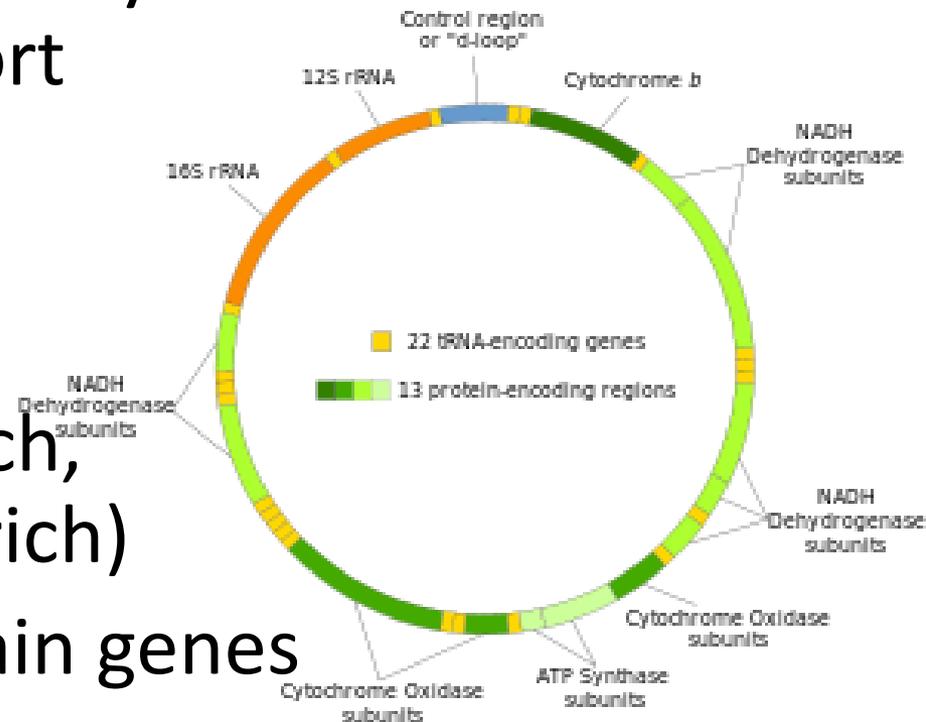

# Mitochondrial DNA

- 2-10 mtDNA copies/mitochondrion
- Double stranded, circular, short (~16,600 base pairs)

# Mitochondrial DNA

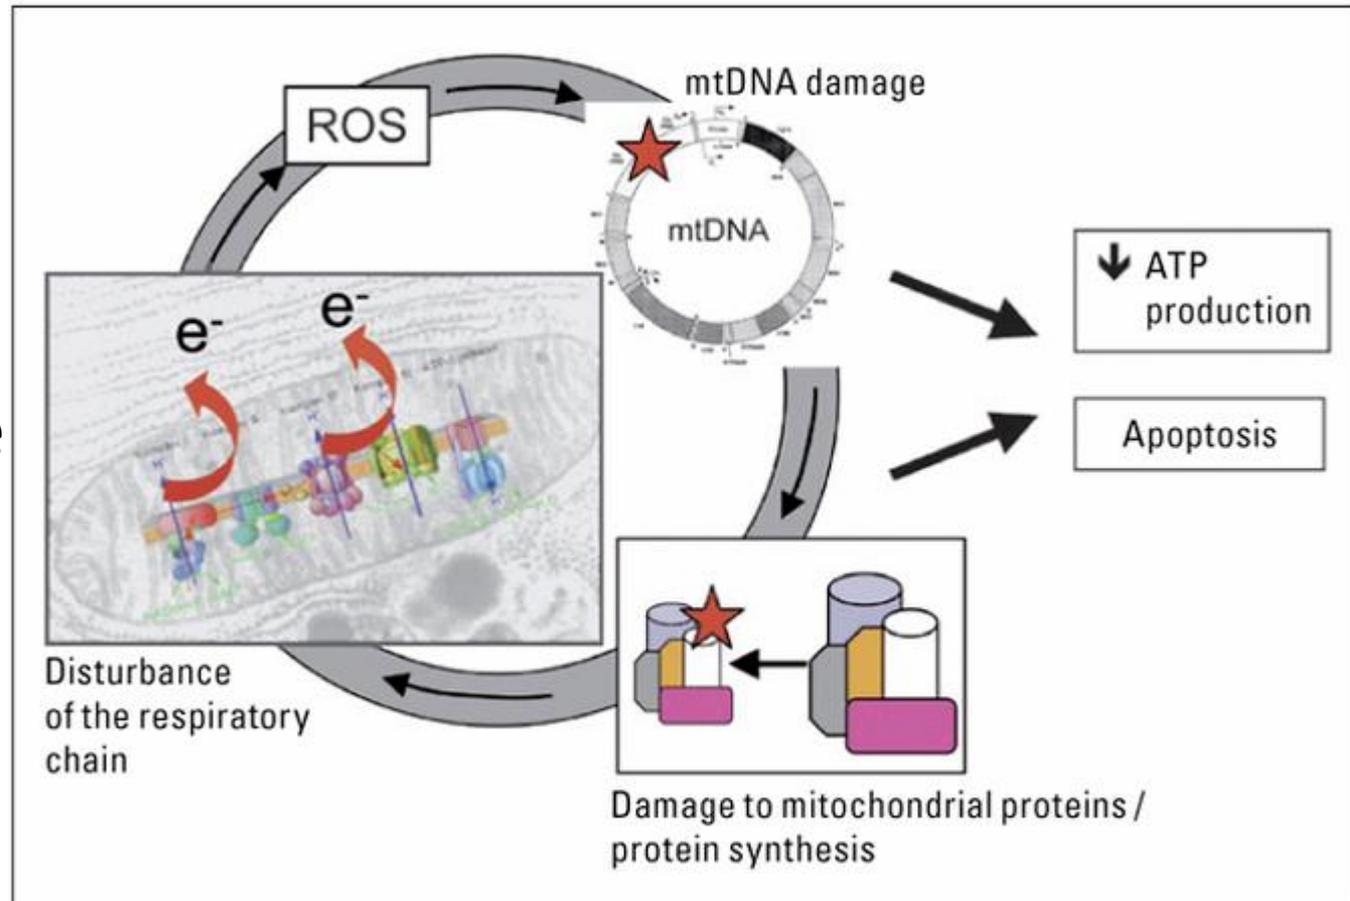

- Codes for only 37 genes (13 for proteins, 22 for tRNA and 2 for rRNA)
- other genes are in the eukaryotic nucleus → posttranslational transport
- the two strands are different by their nucleotide content (one strand is guanine-rich, other strand is cytosine-rich)
- both of the strands contain genes

# Mutation of mtDNA

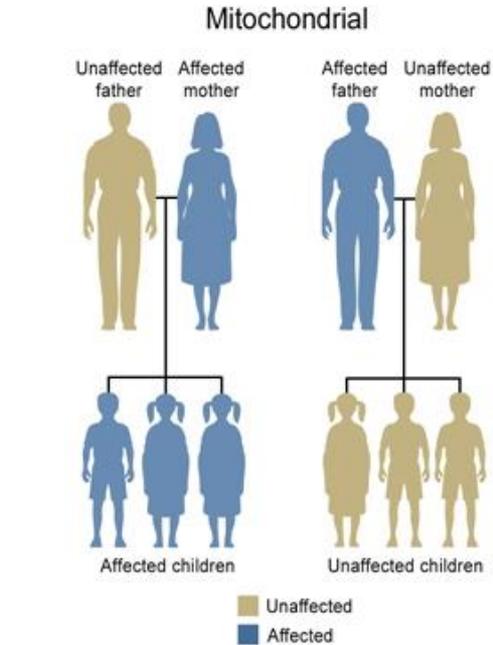

- Free radicals
- No histon proteins
- Proofreading and repair are weak

→ damage of the DNA, proteins and of the inner membrane

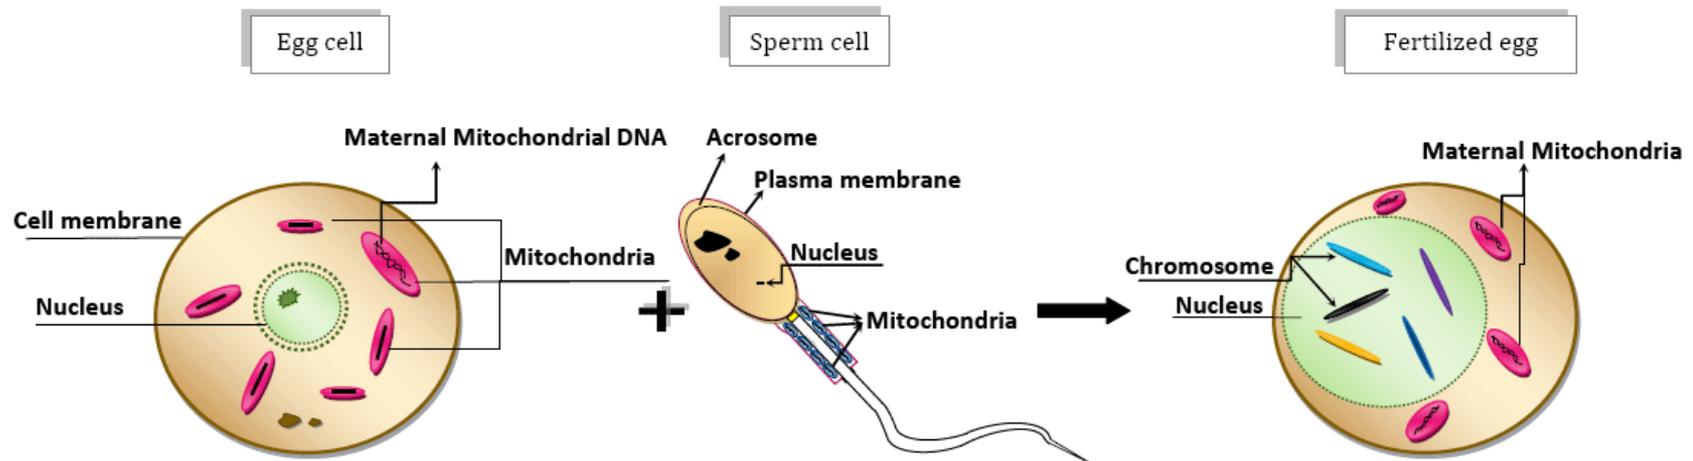

# Inheritance of mitochondria

- Non- mendelian inheritance
- maternal inheritance (from mother to child)

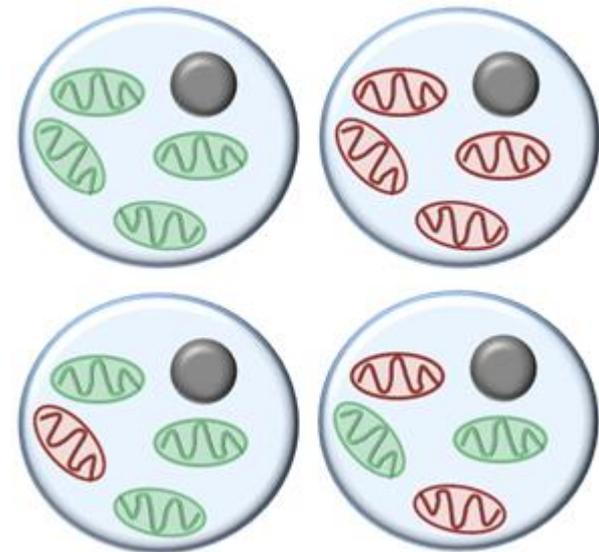

U.S. National Library of Medicine

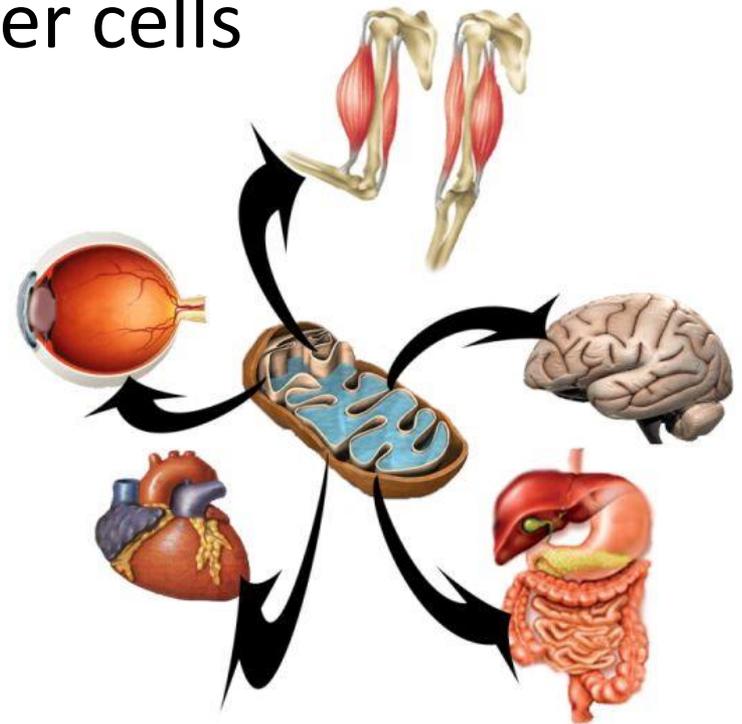

# Inheritance of mitochondria

- Homoplasmy-copies of mtDNA are all identical in a cell (normal or mutated)
- Heteroplasmy- copies of mtDNA are different in a cell (normal and mutated)  
-ratio of mutated mtDNA reaches a treshold → disease

# Mitochondrial diseases

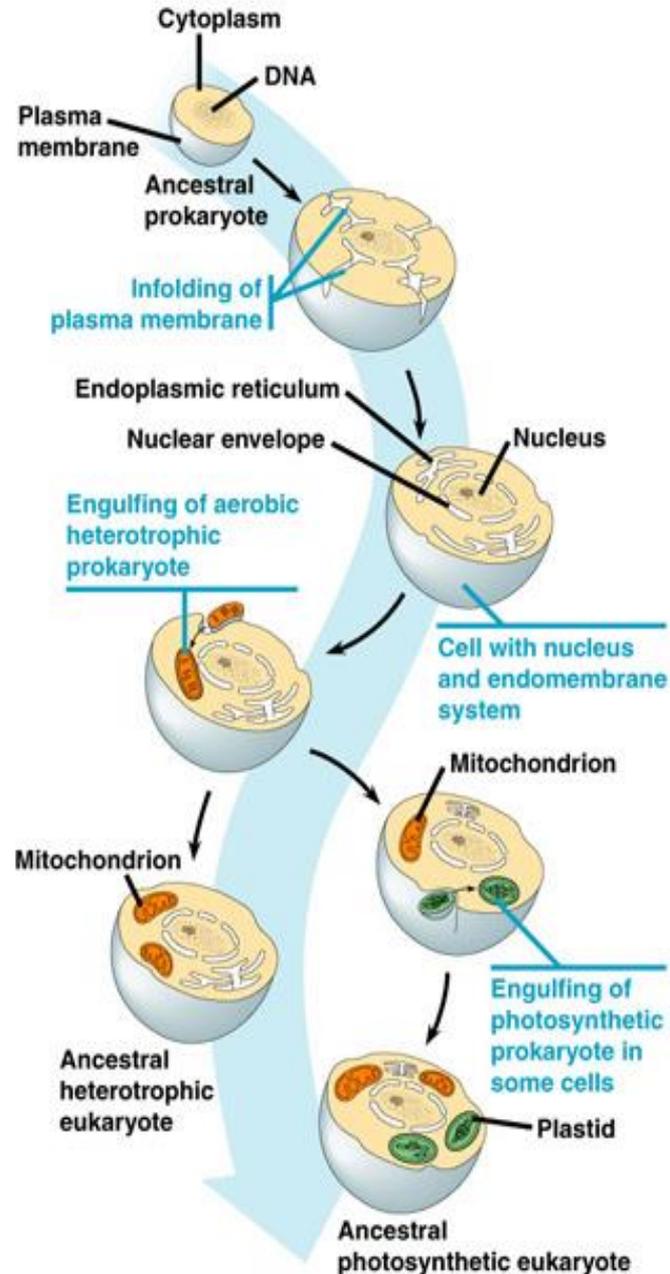

- Sensory organs, muscle, heart, nervous system, pancreas,... are affected → these cells use more energy than other cells
- neurological disorders
- Diabetes mellitus
- blindness
- myopathy (muscular weakness)

# Endosymbiotic theory

- describes the development of eukaryotic cells
- Greek: endon = within, syn = together and biosis = living
- Konstantin Mereschkowski (1910)
- several cell organelles of eukaryotes originate from unicellular organisms

1. infolding of cell membrane → „compartments”
2. engulfing of prokaryotes → mitochondrion, plastids

# Evidences

- formation of new mitochondria and plastids through binary fission
- both mitochondria and plastids contain single circular DNA that is similar to that of bacteria (most of their genes are transferred to the host cell genome)
- ribosomes are like those found in bacteria
- comparison of the genome
- ...
